- 4 Non-Linear Forecasting
- 5 Beyond Hierarchies
- 6 Wrap-up

### **Outline**

- 1 Hierarchical Data and Forecast Reconciliation
- 2 Probabilistic Forecasts
- 3 Quantile Forecasting
- 4 Non-Linear Forecasting
- 5 Beyond Hierarchies
- 6 Wrap-up

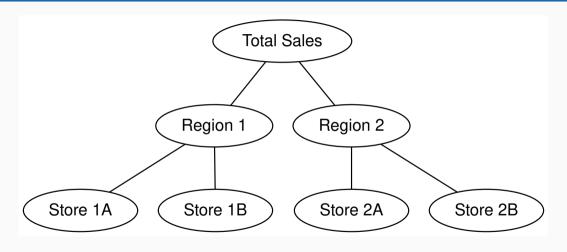

At its most general, **multivariate** data  $\mathbf{y} \in \mathbb{R}^n$  bound together by some constraints.

- At its most general, **multivariate** data  $\mathbf{y} \in \mathbb{R}^n$  bound together by some constraints.
- Typically these constraints are **linear**, although later I will present new work for non-linear constraints.

- At its most general, **multivariate** data  $\mathbf{y} \in \mathbb{R}^n$  bound together by some constraints.
- Typically these constraints are **linear**, although later I will present new work for non-linear constraints.
- Most commonly arise due to an aggregation structure, hence the name 'hierarchical'.

- At its most general, **multivariate** data  $\mathbf{y} \in \mathbb{R}^n$  bound together by some constraints.
- Typically these constraints are **linear**, although later I will present new work for non-linear constraints.
- Most commonly arise due to an **aggregation** structure, hence the name 'hierarchical'.
- Need not be hierarchical, alternative structures are grouped (or crossed) aggregation, or temporal aggregation.

# Hierarchy

# **One representation**

For the simple hierarchy shown earlier:

$$\begin{pmatrix} y_{\text{Tot}} \\ y_1 \\ y_2 \\ y_{1A} \\ y_{1B} \\ y_{2A} \\ y_{2B} \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \times \begin{pmatrix} y_{1A} \\ y_{1B} \\ y_{2A} \\ y_{2B} \end{pmatrix}$$

$$\mathbf{y} = \mathbf{S} \times \mathbf{b}$$

6

Observations will always cohere to the constraints.

- Observations will always cohere to the constraints.
- Forecasts generally will not.

- Observations will always cohere to the constraints.
- Forecasts generally will not.
  - Different forecasts are made by different agents.

- Observations will always cohere to the constraints.
- Forecasts generally will not.
  - Different forecasts are made by different agents.
  - Hard to construct a method that guarantees coherence.

- Observations will always cohere to the constraints.
- Forecasts generally will not.
  - Different forecasts are made by different agents.
  - Hard to construct a method that guarantees coherence.
- This talk is about **two-stage** processes whereby incoherent **base** forecasts are adjusted to be coherent.

- Observations will always cohere to the constraints.
- Forecasts generally will not.
  - Different forecasts are made by different agents.
  - Hard to construct a method that guarantees coherence.
- This talk is about **two-stage** processes whereby incoherent **base** forecasts are adjusted to be coherent.
- Note there is also work on **end-to-end** forecasting (e.g. Rangapuram et al. 2021).

Start with a vector of incoherent forecasts  $\hat{\mathbf{y}}$ .

- Start with a vector of incoherent forecasts  $\hat{\mathbf{y}}$ .
- Recall the characterization earlier with S

- Start with a vector of incoherent forecasts  $\hat{\mathbf{y}}$ .
- Recall the characterization earlier with S
- 'Regress' ŷ on S.

- Start with a vector of incoherent forecasts  $\hat{\mathbf{y}}$ .
- Recall the characterization earlier with S
- 'Regress' ŷ on S.
- Use prediction as reconciled forecasts  $\tilde{\mathbf{y}}$ , i.e.

- Start with a vector of incoherent forecasts  $\hat{\mathbf{y}}$ .
- Recall the characterization earlier with S
- 'Regress' ŷ on S.
- Use prediction as reconciled forecasts  $\tilde{\mathbf{y}}$ , i.e.

$$\tilde{\mathbf{y}} = \mathbf{S}(\mathbf{S}'\mathbf{S})^{-1}\mathbf{S}'\hat{\mathbf{y}}$$

This is called OLS reconciliation.

# **An optimization lens**

■ Ensure that  $\hat{\mathbf{y}}$  and  $\tilde{\mathbf{y}}$  are 'close'.

$$\tilde{\mathbf{y}} = \underset{\mathbf{y}}{argmin}||\mathbf{y} - \hat{\mathbf{y}}||_2$$

# An optimization lens

■ Ensure that  $\hat{y}$  and  $\tilde{y}$  are 'close'.

$$\tilde{\mathbf{y}} = \underset{\mathbf{y}}{argmin}||\mathbf{y} - \hat{\mathbf{y}}||_2$$

Under certain assumptions, this yields the same solution as the regression interpretation.

9

# **An optimization lens**

■ Ensure that  $\hat{y}$  and  $\tilde{y}$  are 'close'.

$$\tilde{\mathbf{y}} = \underset{\mathbf{y}}{argmin}||\mathbf{y} - \hat{\mathbf{y}}||_2$$

- Under certain assumptions, this yields the same solution as the regression interpretation.
- Also has a game theoretic interpretation (see van Erven and Cugliari 2015)

#### **Generalizations**

■ Where OLS works, it makes sense to consider GLS

$$\tilde{\mathbf{y}} = \mathbf{S}(\mathbf{S}'\mathbf{W}\mathbf{S})^{-1}\mathbf{S}'\mathbf{W}\hat{\mathbf{y}}$$

#### **Generalizations**

Where OLS works, it makes sense to consider GLS

$$\tilde{\mathbf{y}} = \mathbf{S}(\mathbf{S}'\mathbf{W}\mathbf{S})^{-1}\mathbf{S}'\mathbf{W}\hat{\mathbf{y}}$$

Setting  $\mathbf{W}^{-1}$  to the covariance matrix of  $\mathbf{y} - \hat{\mathbf{y}}$  optimizes expected squared error loss.

#### **Generalizations**

Where OLS works, it makes sense to consider GLS

$$\tilde{\mathbf{y}} = \mathbf{S}(\mathbf{S}'\mathbf{W}\mathbf{S})^{-1}\mathbf{S}'\mathbf{W}\hat{\mathbf{y}}$$

- Setting  $\mathbf{W}^{-1}$  to the covariance matrix of  $\mathbf{y} \hat{\mathbf{y}}$  optimizes expected squared error loss.
- This is the well-known **MinT method** of Wickramasuriya, Athanasopoulos, and Hyndman (2019).

Another alternative is a geometric view.

- Another alternative is a geometric view.
- The constraints define a linear subspace  $S \subset \mathbb{R}^n$ .

- Another alternative is a geometric view.
- The constraints define a linear subspace  $S \subset \mathbb{R}^n$ .

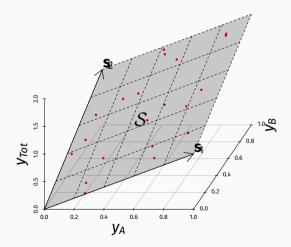

- Another alternative is a geometric view.
- The constraints define a linear subspace  $S \subset \mathbb{R}^n$ .
  - ▶ Sometimes \$ notation is used.
- This can easily be extended to other settings

- lacksquare The reconciled measure  $\tilde{\mu}$  is defined as

$$\tilde{\mu}(\mathcal{A}) = \hat{\mu}(\psi^{-1}(\mathcal{A}))$$

 $m{\mu}$  is the **pushforward** of  $\hat{\mu}$  by  $\psi$ , denoted as  $\psi \# \hat{\mu}$ 

■ This merely defines a way of getting a reconciled distribution from some incoherent base distribution.

- This merely defines a way of getting a reconciled distribution from some incoherent base distribution.
- What is the optimal  $\psi$ ?

- This merely defines a way of getting a reconciled distribution from some incoherent base distribution.
- What is the optimal  $\psi$ ?
- In the point forecasting world the  $\psi$  given by MinT is optimal for squared loss.

- This merely defines a way of getting a reconciled distribution from some incoherent base distribution.
- What is the optimal  $\psi$ ?
- In the point forecasting world the  $\psi$  given by MinT is optimal for squared loss.
- What does optimality even mean for distributional forecasts?

#### **Scoring rules**

■ A scoring rule  $S: \mathcal{P} \times \mathbb{R}^n \to \mathbb{R}$  takes a distributional forecast from a family  $\mathcal{P}$  and an observation and assigns a *score* that measures forecast quality.

### **Scoring rules**

- A scoring rule  $S: \mathcal{P} \times \mathbb{R}^n \to \mathbb{R}$  takes a distributional forecast from a family  $\mathcal{P}$  and an observation and assigns a *score* that measures forecast quality.
- In the context of probabilistic forecasting, it has been proven that choosing  $\psi$  to be the same projection as MinT is optimal for log score when probabilistic forecasts are Gaussian (Wickramasuriya 2023)

### **Scoring rules**

- A scoring rule  $S: \mathcal{P} \times \mathbb{R}^n \to \mathbb{R}$  takes a distributional forecast from a family  $\mathcal{P}$  and an observation and assigns a *score* that measures forecast quality.
- In the context of probabilistic forecasting, it has been proven that choosing  $\psi$  to be the same projection as MinT is optimal for log score when probabilistic forecasts are Gaussian (Wickramasuriya 2023)
- In other cases we can optimize using a data driven approach.

■ Obtain a sequence of base forecasts  $\hat{\mu}_t$  and corresponding realizations  $\mathbf{y}_t$ .

- Obtain a sequence of base forecasts  $\hat{\mu}_t$  and corresponding realizations  $\mathbf{y}_t$ .
- Parameterize  $\psi$  by some parameters  $\theta$  (denoted  $\psi_{\theta}$ )

- Obtain a sequence of base forecasts  $\hat{\mu}_t$  and corresponding realizations  $\mathbf{y}_t$ .
- Parameterize  $\psi$  by some parameters  $\theta$  (denoted  $\psi_{\theta}$ )
- For example,  $\psi(\mathbf{y}) = \mathbf{S}(\mathbf{d} + \mathbf{G}\mathbf{y})$ ,  $\theta = (\mathbf{d}', vec(\mathbf{G})')'$

- Obtain a sequence of base forecasts  $\hat{\mu}_t$  and corresponding realizations  $\mathbf{y}_t$ .
- Parameterize  $\psi$  by some parameters  $\theta$  (denoted  $\psi_{\theta}$ )
- For example,  $\psi(\mathbf{y}) = \mathbf{S}(\mathbf{d} + \mathbf{G}\mathbf{y}), \ \theta = \left(\mathbf{d}', vec(\mathbf{G})'\right)'$
- Optimize the following

- Obtain a sequence of base forecasts  $\hat{\mu}_t$  and corresponding realizations  $\mathbf{y}_t$ .
- Parameterize  $\psi$  by some parameters  $\theta$  (denoted  $\psi_{\theta}$ )
- For example,  $\psi(\mathbf{y}) = \mathbf{S}(\mathbf{d} + \mathbf{G}\mathbf{y}), \ \theta = \left(\mathbf{d}', vec(\mathbf{G})'\right)'$
- Optimize the following

$$\underset{\boldsymbol{\theta}}{argmin} \sum_{\mathbf{t}} S(\psi_{\boldsymbol{\theta}} * \hat{\mu}_{\mathbf{t}}, \mathbf{y}_{\mathbf{t}})$$

Scoring rules that have been used include log score, energy score and variogram score.

- Scoring rules that have been used include log score, energy score and variogram score.
- Paired forecasts and observations can be obtained using rolling or expanding window schemes.

- Scoring rules that have been used include log score, energy score and variogram score.
- Paired forecasts and observations can be obtained using rolling or expanding window schemes.
- Different optimal values of  $\theta$  can be obtained for different forecast horizons.

- Scoring rules that have been used include log score, energy score and variogram score.
- Paired forecasts and observations can be obtained using rolling or expanding window schemes.
- Different optimal values of  $\theta$  can be obtained for different forecast horizons.
- Often draw a sample from  $\hat{\mu}$  rather than work with the distribution itself.

- Scoring rules that have been used include log score, energy score and variogram score.
- Paired forecasts and observations can be obtained using rolling or expanding window schemes.
- Different optimal values of  $\theta$  can be obtained for different forecast horizons.
- Often draw a sample from  $\hat{\mu}$  rather than work with the distribution itself.
- Optimization by first order methods (e.g. SGD).

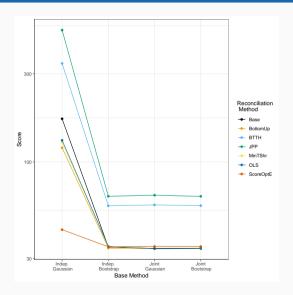

Consider a moderate sized hierarchy (approx 20 variables) of electricity generation from different sources.

- Consider a moderate sized hierarchy (approx 20 variables) of electricity generation from different sources.

- For reasonably well specified models
  - Projections are robust

- Interplay between reconciliation and model misspecification.
- Reconciliation via score optimization most effective when base models heavily misspecified.
- For reasonably well specified models
  - Projections are robust
  - Gains over base forecasts are not as big

- Interplay between reconciliation and model misspecification.
- Reconciliation via score optimization most effective when base models heavily misspecified.
- For reasonably well specified models
  - Projections are robust
  - Gains over base forecasts are not as big
- Reconciliation gives forecaster a 'second chance'.

#### **Outline**

- 1 Hierarchical Data and Forecast Reconciliation
- 2 Probabilistic Forecasts
- 3 Quantile Forecasting
- 4 Non-Linear Forecasting
- 5 Beyond Hierarchies
- 6 Wrap-up

#### **Pinball loss**

Many forecasting problems involve optimizing pinball loss.

$$L_{\alpha}(\mathbf{y},\mathbf{q}) = \alpha(\mathbf{y}_i - \mathbf{q})I(\mathbf{y}_i \geq \mathbf{q}) + (1 - \alpha)(\mathbf{q} - \mathbf{y}_i)I(\mathbf{y}_i < \mathbf{q})$$

#### **Pinball loss**

Many forecasting problems involve optimizing pinball loss.

$$L_{\alpha}(\mathbf{y},\mathbf{q}) = \alpha(\mathbf{y}_i - \mathbf{q})I(\mathbf{y}_i \geq \mathbf{q}) + (1 - \alpha)(\mathbf{q} - \mathbf{y}_i)I(\mathbf{y}_i < \mathbf{q})$$

■ Here, I(.) equals 1 when the statement in parentheses is true, 0 otherwise.

#### **Pinball loss**

Many forecasting problems involve optimizing pinball loss.

$$L_{\alpha}(\mathbf{y},\mathbf{q}) = \alpha(\mathbf{y}_i - \mathbf{q})I(\mathbf{y}_i \geq \mathbf{q}) + (1 - \alpha)(\mathbf{q} - \mathbf{y}_i)I(\mathbf{y}_i < \mathbf{q})$$

- Here, I(.) equals 1 when the statement in parentheses is true, 0 otherwise.
- $\blacksquare$  Quantiles minimize expected pinball loss  $E_Y[L_\alpha(y,q)]$

#### In reconciliation

■ To target quantiles we optimize.

$$\underset{G}{\operatorname{argmin}} \sum_{i=1}^{n} \sum_{t \in \mathcal{T}_{\operatorname{train}}} L_{\alpha}(y_{i,t}, \tilde{q}_{i,t})$$

#### In reconciliation

■ To target quantiles we optimize.

$$\underset{G}{\operatorname{argmin}} \sum_{i=1}^{n} \sum_{t \in \mathcal{T}_{\text{train}}} L_{\alpha}(\mathbf{y}_{i,t}, \tilde{\mathbf{q}}_{i,t})$$

Subject to the constraints

$$\tilde{q}_{i,t} = \underset{q}{\operatorname{argminE}}_{\tilde{Y}_{i,t}} \left[ L_{\alpha}(\tilde{y}_{i,t}, q) \right]$$

# **Optimization**

■ This is an example of **bi-level optimization**.

# **Optimization**

- This is an example of **bi-level optimization**.
- It is further complicated by the fact that pinball loss is not smooth.

## **Optimization**

- This is an example of bi-level optimization.
- It is further complicated by the fact that pinball loss is not smooth.
- It is also complicated by the need to approximate expectations with sample equivalents.

# **Smooth pinball loss**

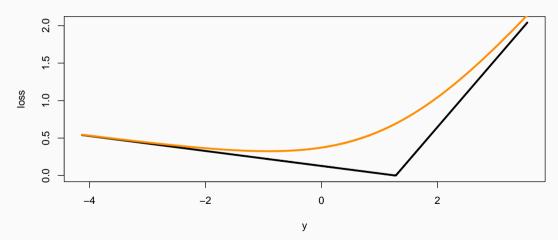

The following function approximates the pinball loss and converges to pinball loss as  $\beta \to \infty$ 

$$L_{\alpha}^{\beta}(y,q) = \frac{1}{\beta} \log \left( e^{\beta \alpha (y-q)} + e^{\beta (1-\alpha)(q-y)} \right)$$

Unlike the pinball function it is smooth, meaning we can use first order methods (like Stochastic Gradient Descent).

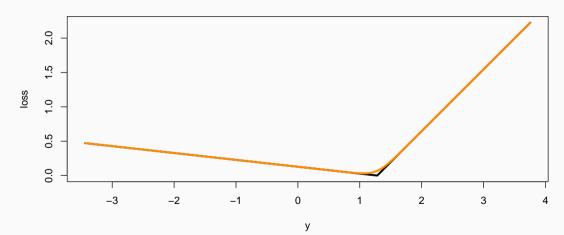

# Smoothed pinball loss ( $\beta$ = 1)

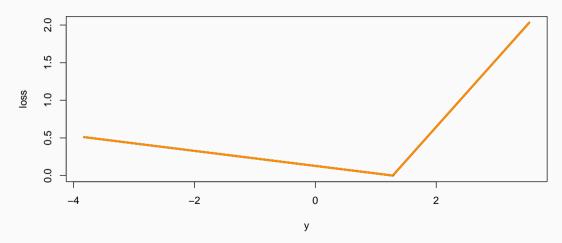

# Smoothed pinball loss ( $\beta$ = 10)

Pinball loss alpha=0.9, q=1.2816

# Smoothed pinball loss ( $\beta$ = 100)

#### Pinball loss alpha=0.9, q=1.2816

#### What we want to solve

$$\underset{G}{\operatorname{argmin}} \sum_{i=1}^{n} \sum_{t \in \mathcal{T}_{\text{train}}} L_{\alpha}(y_{i,t}, \tilde{q}_{i,t})$$

Subject to the constraints

$$\tilde{q}_{i,t} = \underset{q}{\operatorname{argminE}}_{\tilde{Y}_{i,t}} \left[ L_{\alpha}(\tilde{y}_{i,t}, q) \right]$$

#### What we can solve

$$\underset{G}{\operatorname{argmin}} \sum_{i=1}^{n} \sum_{t \in \mathcal{T}_{\text{train}}} \mathsf{L}_{\alpha}^{\beta}(\mathsf{y}_{i,t}, \tilde{\mathsf{q}}_{i,t})$$

Subject to the constraints

$$\tilde{q}_{i,t|t-1} = \underset{q}{\operatorname{argmin}} \sum_{j} L_{\alpha}^{\beta}(\tilde{y}_{i,t}^{(j)}, q)$$

Let f(G) be the problem we want to solve

- Let f(G) be the problem we want to solve
- Let  $f^{\beta}(\mathbf{G})$  be the smooth approximation of pinball loss

- Let f(G) be the problem we want to solve
- Let  $f^{\beta}(\mathbf{G})$  be the smooth approximation of pinball loss
- Let  $f^{(j)}$  the approximation from using J draws.

37

- Let f(G) be the problem we want to solve
- Let  $f^{\beta}(\mathbf{G})$  be the smooth approximation of pinball loss
- Let  $f^{(J)}$  the approximation from using J draws.
- Prove minimizer of approximate problem converges to minimizer of the 'true' problem by proving

- What if the constraints are non-linear?
- For example ratios are common quantities of interest.
  - Mortality rates are Deaths divided by Exposure.
  - Unemployment rates are number of unemployed divided by labor force.
- Both of these examples are also be subject to aggregation.

In general there are C constraints  $g_1(\mathbf{y}) = 0, \dots g_C(\mathbf{y}) = 0$ , or more compactly  $g(\mathbf{y}) = \mathbf{0}$ .

- In general there are C constraints  $g_1(\mathbf{y}) = 0, \dots g_C(\mathbf{y}) = 0$ , or more compactly  $g(\mathbf{y}) = \mathbf{0}$ .
- The level set of points  $\mathbf{y} : g(\mathbf{y}) = \mathbf{0}$  defines a coherent surface or manifold continue to be denoted as S.

- In general there are C constraints  $g_1(\mathbf{y}) = 0, \dots g_C(\mathbf{y}) = 0$ , or more compactly  $g(\mathbf{y}) = \mathbf{0}$ .
- The level set of points  $\mathbf{y} : g(\mathbf{y}) = \mathbf{0}$  defines a coherent surface or manifold continue to be denoted as S.
- Non-linear reconciliation solves the following problem:

- In general there are C constraints  $g_1(\mathbf{y}) = 0, \dots g_C(\mathbf{y}) = 0$ , or more compactly  $g(\mathbf{y}) = \mathbf{0}$ .
- The level set of points  $\mathbf{y} : g(\mathbf{y}) = \mathbf{0}$  defines a coherent surface or manifold continue to be denoted as S.
- Non-linear reconciliation solves the following problem:

$$\tilde{\mathbf{y}} = \underset{\mathbf{y}}{argmin}(\mathbf{y} - \hat{\mathbf{y}})'\mathbf{W}(\mathbf{y} - \hat{\mathbf{y}})$$

■ Subject to  $\mathbf{y} \in \mathcal{S}$ .

Note focus is still on point forecasts.

- Note focus is still on point forecasts.
- First consider case of convex constraints.

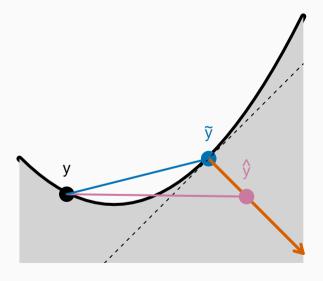

- Note focus is still on point forecasts.
- First consider case of convex constraints.
  - Reconciliation guaranteed to improve base forecast, but only in hypograph.

- Note focus is still on point forecasts.
- First consider case of convex constraints.
  - Reconciliation guaranteed to improve base forecast, but only in hypograph.
- For more general constraints

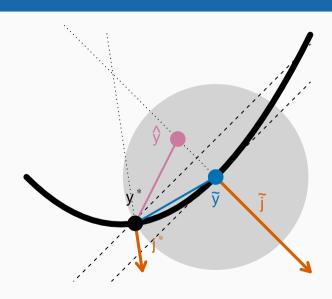

- Note focus is still on point forecasts.
- First consider case of convex constraints.
  - Reconciliation guaranteed to improve base forecast, but only in hypograph.
- For more general constraints
  - Find closest point on the coherent manifold equidistant from the base and reconciled forecast.

- Note focus is still on point forecasts.
- First consider case of convex constraints.
  - Reconciliation guaranteed to improve base forecast, but only in hypograph.
- For more general constraints
  - Find closest point on the coherent manifold equidistant from the base and reconciled forecast.
  - This defines a ball in which reconciliation always outperforms base forecasts.

# Convex Function: Hypograph

# **Any function**

### **Radius of the Ball**

■ The radius of the ball on the previous slide is given by

$$r = \sqrt{\kappa' J^{*'} J^{*} \kappa + \mu \kappa' J^{*'} \tilde{J} \lambda + \frac{\mu^2}{4} \lambda \tilde{J}' \tilde{J} \lambda}$$

#### **Radius of the Ball**

■ The radius of the ball on the previous slide is given by

$$r = \sqrt{\kappa' \mathbf{J}^{*'} \mathbf{J}^{*} \kappa + \mu \kappa' \mathbf{J}^{*'} \tilde{\mathbf{J}} \lambda + \frac{\mu^{2}}{4} \lambda \tilde{\mathbf{J}}' \tilde{\mathbf{J}} \lambda}$$

 $\mathbf{J}^*$  and  $\tilde{\mathbf{J}}$  are gradients of the constraint evaluated at  $\mathbf{y}^*$  and  $\tilde{\mathbf{y}}$  respectively.

#### **Radius of the Ball**

■ The radius of the ball on the previous slide is given by

$$r = \sqrt{\kappa' \mathbf{J}^{*'} \mathbf{J}^{*} \kappa + \mu \kappa' \mathbf{J}^{*'} \tilde{\mathbf{J}} \lambda + \frac{\mu^{2}}{4} \lambda \tilde{\mathbf{J}}' \tilde{\mathbf{J}} \lambda}$$

- $\mathbf{J}^*$  and  $\tilde{\mathbf{J}}$  are gradients of the constraint evaluated at  $\mathbf{y}^*$  and  $\tilde{\mathbf{y}}$  respectively.
- $\blacksquare$   $\lambda$  and  $\kappa$  are Lagrange multipliers associated with certain optimization problems.

■ This theory tells us that non-linear forecast reconciliation is more likely to succeed when

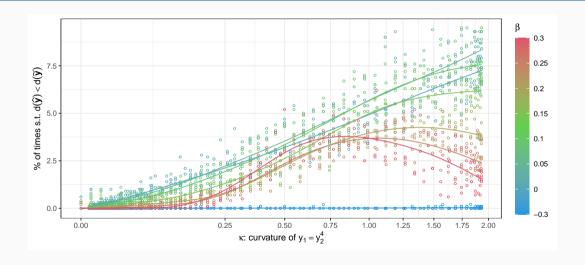

- This theory tells us that non-linear forecast reconciliation is more likely to succeed when
  - Base forecast is far from coherent manifold.

- This theory tells us that non-linear forecast reconciliation is more likely to succeed when
  - Base forecast is far from coherent manifold.
  - The constraint function has lower curvature.

- This theory tells us that non-linear forecast reconciliation is more likely to succeed when
  - Base forecast is far from coherent manifold.
  - The constraint function has lower curvature.
  - When reconciled forecast is in a high probability region of the true DGP.

- This theory tells us that non-linear forecast reconciliation is more likely to succeed when
  - Base forecast is far from coherent manifold.
  - The constraint function has lower curvature.
  - When reconciled forecast is in a high probability region of the true DGP.
  - When some constraints are convex and the bast forecast is more likely to lie in the hypographs of these constraints.

## **Simulation results**

Annual (1969-2019) data on

- Annual (1969-2019) data on
  - ► Exposure (E)

- Annual (1969-2019) data on
  - Exposure (E)
  - ► Deaths (*D*)
